Early Farmer Validation

Before formal pilot deployment, the team conducted direct field engagement with three farmers in Andhra Pradesh to better understand real-world agricultural decision-making, disease management practices, and operational challenges.

These engagements focused on:

- Crop disease identification workflows
- Pesticide usage patterns and application timing
- Farmer decision-making during disease outbreaks
- Information gaps between symptom detection and intervention
- Economic impact of delayed treatment actions

Key findings included:

- Farmers often rely on visual symptoms before taking action, reducing the available treatment window.
- Disease outbreaks can result in significant yield losses when interventions are delayed.
- Existing advisory systems are largely reactive rather than predictive.
- Farmers expressed interest in receiving earlier warnings and actionable recommendations when linked to clear economic outcomes.
- Disease management decisions are frequently constrained by limited access to timely, localized intelligence.

While these engagements do not constitute statistically significant pilot validation, they provided important customer discovery insights and confirmed that disease prediction, early intervention, and decision-support remain high-value problems within the target market.

These learnings directly informed the company's prediction-first strategy and the design of its AI-powered agricultural intelligence platform. The next phase involves structured pilot deployments, outcome measurement, and collection of labeled field data to validate prediction accuracy and economic impact at scale.
